

### Final

- 1) Clear your desk top of all **handwritten** papers and personal notes. You may keep **only** the textbook, your test paper, and a pencil.
  
- 2) Read through the test completely and work the problems you can, leaving the difficult ones until last.
  
- 3) Keep your eyes on your own paper. Cheating will not be tolerated!
  
- 4) Work problems on the back of the previous page if necessary.
  
- 5) **Show your work!**

NAME: \_\_\_\_\_

## Question 1

Five tasks are to be scheduled using the *Earliest Deadline First* algorithm. The tasks' arrival times ( $a_i$ ) – i.e. the times at which the tasks become *Ready* – the tasks' execution times ( $e_i$ ) and the tasks' deadline ( $d_i$ ) are displayed below.

	$T_1$	$T_2$	$T_3$	$T_4$	$T_5$
$a_i$	0	0	2	3	6
$e_i$	1	3	2	2	2
$d_i$	2	5	4	10	9

- Assuming a Non-preemptive OS, draw the time diagram with the execution of the five tasks scheduled by the *EDF* algorithm. (Explain why!)
- Did any task not meet the deadline?
- Re-do the two parts above assuming a preemptive scheduling.

## Question 2

Verify the schedulability of the following two sets of tasks according to the Rate Monotonic algorithm. If the tasks are schedulable, construct the schedule according to RM.

(a)

	$T_1$	$T_2$	$T_3$
$e_i$	2	2	2
$p_i$	6	8	12

(b)

	$T_1$	$T_2$	$T_3$
$e_i$	1	2	3
$p_i$	4	6	8

## Question 3

A shared memory scheme is to be used as a means of exchanging blocks of data between two tasks,  $T_0$  and  $T_1$ . One of the tasks is on the main processor, and the other is executing on an external device. The shared area occupies 2K of memory in a 16Kx8 SRAM; however, the number of bytes written with each exchange is variable.

- (a) Present a design for the shared memory system.
- (b) Using a UML sequence diagram or another clearly defined diagram, explain how your memory system works by describing a complete cycle that includes the following: a write by  $T_0$ ; a read by  $T_1$ ; a write by  $T_1$ ; and a read by  $T_0$ .
- (c) How does each task know when data is available and how much data is available?
- (d) Are there any potential problems with your design?
- (e) How would your design change if three tasks were involved in the exchange?

## Question 4

1. Which type of socket communication is considered to be more reliable: Stream or Data Gram? Explain how each type works and the reason for one being more reliable.

2. What function is used to map a variable/pointer to a register (such as port B) in kernel space?

3. Instead of a main section for the case of a user space program, kernel modules have two generic sections of code. What are their names? What is their purpose/function? When are they run?

4. What is it called when a process is perpetually denied necessary resources? Give an example.

5. What mechanism can be used to pass data between a realtime task and a Linux process? Explain how it works.

6. If there is a realtime task that periodically writes to a FIFO, and two Linux processes open that same FIFO and try to read data from it, what is the behavior?

7. If I create a thread with id = tid and call `pthread_join(&tid,0)` in main, what happens?

8. Please order the following by their priority (1 highest priority 4 lowest priority)

- \_\_\_ Realtime Task
- \_\_\_ linux process
- \_\_\_ Realtime Interrupt
- \_\_\_ Linux interrupt
